Varietal Experiments With Tobacco*

The production of tobacco in West Virginia is largely confined to section embracing eight counties in the southwestern part of the te. These counties are Cabell, Lincoln, Putnam, Mason, Wayne, ekson. Boone, and Kanawha, of which the first three named produce proximately five million of the seven and one-half million pounds oduced annually in the state.

The varieties of tobaceo grown in this section belong, in the main, the Burley type which is used primarily for the manufacture of twing and smoking tobaccos. Inasmuch as no definite experimental dence as to the relative values of the different varieties grown this section was available, varietal experiments were begun in the ing of 1922, at the Lakin substation in Mason County.

EXPERIMENTAL METHODS AND SOURCES OF VARIETIES

Soil Treatment

The plots on which the varietal experiments were carried out were sted on first bottom land near the Ohio River. The soil was a highly ductive Huntington silt loam which had been in grass for several rs previous to its use for experimental purposes. The grass sod plowed in 1921 and planted to corn. In two of the four years in the varietal experiments were underway, tobacco followed corn in the other two years tobacco followed oats.

No fertilizer was applied to the tobacco or to any crop preceding. The cropping plan followed and the lack of a fertilizer treatment not necessarily recommended practices. This procedure was folded in this case because of certain other experiments under way.) the spring of 1925 a heavy cover crop of rye was turned under for teeo.

Varieties

In Table 1 are listed the source of seed and the seventeen varieties strains of tobacco which were tested during the four-year period,

^{&#}x27;The tobacco experiments at Lakin are carried on in cooperation with the Office of cco Investigations, Bureau of Plant Industry, United States Department of ulture. The writers are indebted to Dr. W. W. Garner, Chief of that Office, for ble suggestions and for the photographs used in this bulletin. Submitted for publication May, 1926.

from 1922 to 1925, inclusive. Seed of most of the varieties was betained from the United States Department of Agriculture, Office Tobacco Investigations. Five strains were obtained from the Kentuc Agricultural Experiment Station, and one strain from the Huntingor Tobacco Warehouse.

The variety designated as W. B. U. V. is a strain of drooping a Burley, resistant to root-rot, which was developed at the Univer to f Wisconsin. The five lots designated as S. B. No. 1, No. 9, No. 9a, To 10 Ba, and No. 10 Fa, were, at the time of their introduction, third a fourth generation selections made in a cross between W. B. U. V. Judy's Pride, a strain of Standup Burley. Beinhart is a pure a selection of the drooping type of Kentucky White Burley. The standard A. S. 7 is a selection from Vimont-Kelley and is resistant to root of the history of the strain grown as Kentucky Selection is not know.

TABLE 1.—Tobacco Varieties Tested and Sources of Seed with Reaction Root-rot and Character of Growth.

Names of Varieties or Strains	Sources of Seed	Reaction to Root-rot	Characte of Growth
Kelley	Ky. Exp. Station	Non-resistant	Standup
S. B. No. 1	U. S. Dept. of Agr.	Resistant	Standup
No. 9	U. S. Dept. of Agr.	Resistant	Standup
No. 9a	U. S. Dept. of Agr.	Resistant	Standup
No. 9Ba	U. S. Dept. of Agr.	Resistant	Standup
No. 9Fa	U. S. Dept. of Agr.	Resistant	Standup
Kentucky Selection	Ky. Exp. Station	Resistant	Standup
A. S. 7	Ky. Exp. Station	Resistant	Standup
Judy's Pride	U. S. Dept. of Agr.		Standup
Pepper	Ky. Exp. Station		Standup
Beinhart Scl. 1917	U. S. Dept. of Agr.		Non-stand
W. B. U. V.	U. S. Dept. of Agr.	Resistant	Non-stand
Halley	U. S. Dept. of Agr.		Non-stand
White Twist Bud	U. S. Dept. of Agr.		Non-stand
Red	Ky. Exp. Station		Non-stand
Lockwood	U. S. Dept. of Agr.	Non-resistant	Non-stand
Lockwood	Huntington Tobacco		
	Warehouse	Non-resistant	Non-stand

Table 1 also shows the reaction of some of the strains of toble to root-rot and the growth habit ("standup" or "non-standup" all the strains in the test. The "standup" types have erect lewhereas the "non-standup" types have more or less drooping level.

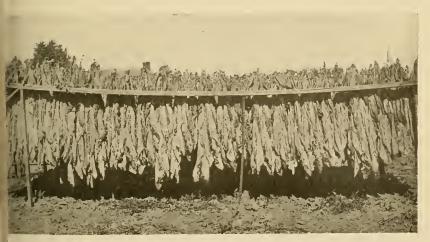

Growing the Crop

The plants for the varietal experiments were produced in the unmanner. Seed was sown about the middle of March in a prep

red-bed at the rate of a scant teaspoonful per 100 square feet of urface. The seed was mixed with ashes to facilitate a uniform distrintion in sowing. After the seed was sown the surface of the entire bed bed was tramped firmly and then covered with a good grade of bbacco muslin. It was necessary, of course, to keep the seed bed well ratered. The seedlings were transplanted to the plots between June 1 and 10.

The plants were grown in rows $3\frac{1}{2}$ feet apart and spaced 18 inches part in the rows. During the first three years of the experiment each lot was made up of three rows with fourteen plants per row. Only be twelve inner plants of the middle row were harvested for the yield ata. In 1925 each plot was made up of four rows of the same length in previous years and the yield record was obtained from twenty-pur plants of the two inner rows. End plants were disearded. In 1923 each variety was grown in five plots, and in 1922, 1924, and 1925 in four plots, systematically distributed over the entire experimental eld. During the latter two years every third plot was used as a heek.

When the tobacco on any particular plot was fully matured, the alks were split, cut, and then spudded. Six plants were placed on a ick. In this condition, they were transported to a scaffold where they remained until well wilted and then were hung in the tobaccouring barn.

A scaffold in the field to facilitate the wilting of tobacco.

Each year the tobacco was carefully graded. The sticks of tobacco were taken to a conditioning cellar until in proper "case" for handling. A sky-light in the grading room increased the intensity and uniformity of the light.

When the leaves were stripped from the stalks they were divided into a maximum of sixteen different grades, dependent on quality. The principal grades recognized by the Burley Tobacco Growers Cooperative Association are: flyings; B, trash; C, lugs; F, heavy tips; F. S., smok- nation.

Grading

A tobacco plant with a 16-pound mar D, bright leaf; E, red leaf; paper bag in place to prevent cross-po

ing tip; C. W., cigarette wrapper; and T. W., twist wrapper. Each these grades, except the "smoking tip" and the two "wrappers," divided into seven classes, number one being the best and numb seven the poorest of a particular grade. In 1925, through the cou esy of the Huntington Branch of the Burley Tobacco Growers' operative Association, it was possible to study the general relation tween the grading of the varieties at the substation and the offic grading of the same varieties, at Huntington. The results of the study are recorded in Table 2.

The vertical columns in Table 2, numbered from one to sixted contain the grades of tobacco made at the Lakin substation, and t twenty-two horizontal rows, labeled A7, A6, etc., contain the offic grades of tobacco made at Huntington. Beginning at the upper le hand corner of Table 2 the official grades reading from the top do and the grades made at the substation reading from left to right a arranged in the same order. Although the official grades and the st station grades do not exactly correspond, the relative position of t grades in one system as arranged in the table corresponds with the in the other system. In general, the substation grades are somewh more inclusive than the official grades.

TABLE 2.—Correlation Between the Official Tobacco Grades of the Burley Tobacco Growers' Cooperative Association and the Grades Established at the Lakin Substation for the Varieties of Tobacco Grown at Lakin in 1925.

Under substation Grade 1, 105 samples were found which we placed in this grade. This same tobacco at Huntington was placed mainly in official grades A7 and A6. Similarly, there were 105 saples which were placed in substation Grade 2, and this same tobaccowas placed chiefly in official grade B6. It is evident from Table 2 the in general there was a fairly close agreement between the substation grades and the official grades, although considerable variation occurry in certain instances.

In 1925 the difference between the average value of the variets per acre, based on the official grades, and that based on the substating grades, was \$1.80. Prior to 1925, only the substation grades were avaable and it was upon the basis of these grades that yields and value were determined. In view of the correlation of grades by the to systems, the yields and values based on the substation grades may considered as a trustworthy index of the yields and values based the official grades.

Data Collected in 1925

As has been previously stated, the tobacco produced on each print 1925 was first graded and labeled, and then shipped to the Huntirton Branch of the Burley Tobacco Growers' Cooperative Association where it was regarded according to official standards and then sold the leaf tobacco market. The average yield of tobacco in pounds pracre and its value for each variety are shown by grades in Table 3.

In columns 2, 4, 6, and 8 are given the yields per acre in pount for grades A7 and A6, A5, and A4, respectively. (These yields a recorded in round numbers only. On the other hand the values peorded in the adjacent columns were computed by multiplying the weight, carried to one decimal, by the auction price per hundred pounds, which may be found at the bottom of the table.) Of the forclasses of tobacco just mentioned, A4 on the average commands the highest price on the market. Considering all the classes of the grade (flyings) together, it is apparent that Lockwood (U. S. D. A and White Twist Bud each produced considerable more tobacco of the grade than did any other variety in the test. Beinhart, Judy's Pric No. 10 Ba, No. 9a, and S. B. No. 1 each produced somewhat more that 250 pounds of A grade tobacco. The least amount of this grade tobacco was produced by Pepper which was closely followed by A. 7 and No. 10 Fa.

In a similar manner, the yields of the several varieties and strai of tobacco, with respect to grades B, C, D, E, and F, might be d cussed. This does not seem worth while, however, in view of the fa

at the data in Table 3 are from only one year's work. The table is blished in extended form, primarily to show the different grades of pacco produced by the several varieties in the test.

The values of the various grades at the time the 1925 crop was rketed are also shown. In general, grades A4, B7, B6, B5, B4, B3, and C5 brought the highest prices per pound, whereas grades E7, F4, and F5 brought the lowest. Considering the last four grades gether, it may be of some interest to point out which varieties proceed relatively high and which relatively low yields. Lockwood (U. D. A.) was the highest producer of the low grades with a total of 4 pounds, and the Huntington strain of Lockwood came second with otal of 379 pounds. The varieties No. 9, No. 10 Ba, Kentucky Selector, A. S. 7. Beinhart, and Halley ranged in production of these interior grades from 306 to 337 pounds. Two varieties gave low yields, mely, Pepper with a total of 163 pounds and Red with a total of 167 unds.

The ratios (expressed in percentages) of the total average yield clumns 8, 10, 12, 14, 16, 18, 20, and 22, Table 3) of the aforemenned more valuable grades, to the total average yield (column 46) the crop for each variety in 1925, have been calculated and are given the following list, in which the varieties are arranged in a descend-corder with regard to their ratios. In other words, the varieties ich are named first produced the greatest relative amount of high and tobacco. The varieties together with their percentages of good and tobacco are as follows: Kelley, 58; Pepper, 55; No. 10 Ba, 51; ly's Pride, 41; No. 10 Fa, 40; No. 9, 37; A. S. 7, 33; Lockwood (U. D. A.), 31; W. B. U. V., 30; Lockwood (Huntington), 30; Beinhart, Kentucky Selection, 28; No. 9a, 26; Red, 22; S. B. No. 1, 21; Hall, 18; and White Twist Bud, 13. It is apparent that in 1925 Kelley, pper, and No. 10 Ba produced the highest percentages, by weight, the better grades of tobacco.

DATA COLLECTED DURING FOUR YEARS

It has already been stated that in 1922, 1923, and 1924 the several rieties and strains of tobacco in the experiments herein reported be graded only at the Lakin substation. The tobacco on each plot is graded and the weight of each grade determined in a manner illar to that followed in 1925. Each grade was given a value based current market prices for that particular year. In this way the a were recorded and collected in a table each year somewhat like to be a except that the yields and values were based on the tobacco des made up at the substation.

TABLE 3.-Average Yield of Tobacco in Pounds Per Acre and Its Value by Grades as Determined on the Huntington Market, for Each of the Seventeen Varieties and Strains Grown at the Lakin Substation in 1925.

*Total weights by variet es based on yields for each grade and recorded to one decimal, but with fractions dropped in totals.

The total average yield of tobacco in pounds per acre and e estimated total value for each variety, for each of the three yes 1922, 1923, and 1924, are brought together in Table 4. In the satable are shown the total average yields and the actual values of 1925 crop, based on the official grades, on the Huntington market.

In column 1 of Table 4 the varieties and strains of tobacco arranged according to the values of their average annual yields, what are recorded in column 11. The average annual value for any pticular variety was obtained by adding together the yearly values f that variety recorded in columns 3, 5, 7, and 9 and dividing the substitute form. The average yields in column 10 are obtained in a similar manner. The value per hundred pounds of tobacco (column 12) is any variety was computed by dividing the average value of the variety by its average yield in pounds and multiplying the quotic by 100.

Considering the varieties which were grown for four years, its apparent from column 11 that there were four of them whose yies had an average annual value somewhat greater than \$500 per ac. These varieties were White Twist Bud, Red, Pepper, and Kelley, which, the first named variety had considerably the highest value three varieties with the lowest average annual value were 1. 10 Fa, W. B. U. V., and No. 9.

The rank of the four varieties which gave the highest average yields (column 10) is the same as their rank with respect to average annual values. The average yield per acre of White Twist Bud heavy dark tobacco) was 2,264 pounds; of Red, 2,144 pounds; Pepper, 2,043 pounds; and of Kelley, 2,016 pounds. The first traineties gave average annual yields of more than 100 pounds in except of the last two varieties.

With respect to average values per hundred pounds of tobac (column 12), Kelley (\$25.00) ranked first, Pepper (\$24.73) second, R (\$23.66) third, and White Twist Bud (\$23.55) fourth. It should noted that the rank of these four varieties with respect to avera values per hundred pounds is just the reverse of what it was wi respect to average yields (column 10) and average values (column 11). The extreme difference in the average values per hundred poun of the four varieties is \$1.41.

Beinhart was grown in only three of the four years in which t experiment was under way, but in each of those three years it rank near the top with respect to yield and value.

CONCLUSION

Under the conditions of the tobacco varietal experiments described in this bulletin, the varieties White Twist Bud, Red, Pepper, and Kelphad the greatest average values per acre for the four years the expense was under way. Kelley and Pepper were somewhat superior quality to White Twist Bud and Red.

On the basis of only three years' work, Beinhart gives promise being a high yielder for the locality in which it was tested.
